(54) **Connection device for corrugated pipes**

(57) It comprises two sleeve-like bodies (1,2) with complementary threaded sections for mutual engagement. One body (1) presents an inner crown (7) of lugs (9) which fit around a corrugated pipe (23) and press it against a frusto-conical portion (18) provided in the other body (2). The lugs (9) are biased in radial direction

by a cylindrical projection (19) of the body (2), which penetrates a gap -7a- existing between the lugs (9) and the inner side of the body (2). When the body (1) is unscrewed, the lugs (9) draw the pipe (23) outwards, thus facilitating its disengagement from the device.

EP 0 728 977 A1

Description

The present invention refers to a connection device for corrugated pipes of the type used to protect electrical cables and in other similar applications.

BACKGROUND OF THE INVENTION

Many devices exist for the connection of corrugated pipes, but in order to achieve good watertightness they have to be supplemented by sealing gaskets which complicate the assembly and make the device more expensive.

Notable amongst these devices are those which comprise, at least, two sleeve-like bodies, which are complementary and can be coupled together by screwing or another similar system, one of said bodies presenting flexible lugs with a tooth-shaped projection at its end, for anchoring into one of the ring-shaped grooves of the corrugated pipe; thanks to the gripping action which the other body exerts against the lugs.

As described above, this known devices require the assistance of a flexible gasket to ensure the watertightness of the joint. In other embodiments, the part provided with the flexible lugs also presents an internal tubular extension, around which are situated the lugs, leaving a gap between them and the extension, into which fits the end of the pipe to be jointed on. This type of connection device has the drawback that the tubular extension limits the possibilities of use of the device to pipes of a specific diameter, with no possibility of fitting to pipes of different diameters, while it also reduces the inner pitch of the pipes to be connected.

DESCRIPTION OF THE INVENTION

The connection device of the invention has been designed to solve the disadvantages outlined. The device connects a corrugated pipe to a junction box with absolute mechanical security and watertightness, easily and without the need to use supplementary gaskets.

The connection device for corrugated pipes according to the invention comprises at least two sleeve-like bodies, each moulded in a single piece and having a certain amount of flexibility, which are complementary and can be coupled to each other by threaded engagement or another similar system, one of said bodies having a plurality of flexible lugs with teeth-like projections at their ends, intended to remain secured in one of the ring-shaped grooves of a corrugated pipe due to the gripping action that the other body exerts against the lugs upon coupling with the first body; it is characterized in that said lugs extend inwards from a mouth of the body, and are arranged forming a circular crown spaced apart a certain distance from the inner side of the body, thus defining a ring-shaped gap, while the other body has a frustoconical opening and a cylindrical extension with a bevelled edge to assist its insertion under pressure into said gap, the inner diameter of said projection

being smaller than the outer diameter of the crown formed by the lugs and its thickness being greater than the width of said ring-shaped gap, so that the cylindrical extension compresses the lugs against the outer surface of the corrugated pipe, thus keeping the tooth-shaped projections secured into one of the grooves thereof, in order to move the end of the pipe towards the frusto-conical opening, against which it fits forming a watertight seal.

In a preferred embodiment, the body provided with the crown of lugs has an inwardly bevelled edge to guide the introduction of the pipe inside the body, and is provided on its outer surface with projections and recesses to assist its handling in rotation.

Advantageously, the body compressing the lugs around the pipe is provided with a polygonal nut-like outer surface.

Also advantageously, the two bodies are provided with a mutually retaining device which engages them loosely in an optimum operating position, and they are supplied for use in this engaged condition.

Preferably, the body provided with the crown of lugs on one end is provided with a slot on the other end, while the other body is provided with a projecting flexible tongue for engagement into said slot.

BRIEF DESCRIPTION OF THE DRAWINGS

For a better understanding of all that is set out in the present specification, some drawings are attached which, solely by way of example, show a particular embodiment of the connection device.

In the drawings, Figure 1 is a section in exploded form of the components of the device and the corrugated pipe; and Figure 2 is a section of the device with the components assembled in two positions, one with the pipe inserted therein but prior to applying the securing system, and the other with the securing system applied and the pipe fitted into the frusto-conical opening.

DESCRIPTION OF A PREFERRED EMBODIMENT

The connection device consists in the drawings of two sleeve-like bodies, indicated by references 1 and 2, each moulded in a single piece and having a certain flexibility. The body 1 presents on the outside a faceted form, with projections and recesses or the like, to facilitate its handling in rotation. This body comprises two sections: a cylindrical section 3 having an inner thread 4 and a frusto-conical section 5 having a bevelled mouth 6 from which departs inwards a cylindrical crown 7 provided with a plurality of transversal cuts 8 extending as far as the mouth 6, between which are formed a plurality of flexible lugs 9 with teeth-like projections 10 oriented towards the centre of the body 1. The lugs 9 are spaced apart from the inner side of section 5 of the body 1, thus leaving a ring-shaped gap 7a.

The body 2 includes an outer projection 11 of polygonal nut-like outline, to facilitate the fitting of a wrench. This projection divides the body 2 into two sections: a cylindrical section 12 with external thread 13 and a wider section 14 with external thread 14a complementary to the thread 4 of the body 1. Section 14 presents a mouth 15 whose edge has an internal bevel 16. Section 14 is provided on the inside with a cylindrical opening 17 and a frusto-conical opening 18. On the outside, section 14 presents at one end a threadless cylindrical extension 19, on which the mouth 15 with the bevel 16 is located. The inner diameter of the opening 17 and the extension 19 is smaller than the outer diameter of the crown 7 formed by the lugs 9. Moreover, the thickness of the cylindrical extension 19 is greater than the width of the ring-shaped gap 7a.

The body 1 is provided with a slot 20 on one edge 21 opposite the mouth 15. In turn, section 14 of the body 2 is provided with a flexible tongue 22 which projects radially from its outer surface.

In order to facilitate the use of the device, after their manufacture the bodies 1 and 2 are screwed on each other until the tongue 22 is engaged into the slot 20. In this position the two bodies are slightly secured to each other, thus avoiding their accidental displacement.

Furthermore, the cylindrical extension 19 has not yet been inserted into the ring-shaped gap 7a, so the lugs 9 yield under the pressure of the corrugated pipe, whose outer diameter is slightly greater than the inner diameter of the projections 10.

For its use the device has to be secured, using the thread 13, to the corresponding input for cables, and one end of the pipe 23 is then inserted through the bevelled mouth 6 of the body 1 until it reaches the frusto-conical opening 18; body 1 is then threaded on body 2, the tongue 22 yielding upon its housing in the cavity 25 while the tooth-shaped projections 10 are inserted in one of the grooves 24 of the pipe 23, so that the latter advances with longitudinal movement; this makes the pipe 23 penetrate more fully into the body 1, while its end rests under pressure in the frusto-conical opening 18, because the teeth 10 of the lugs 9 push it axially. Furthermore, the lugs 9 close like clamps around the pipe 23 because the cylindrical extension 19 which penetrates into the ring-shaped gap 7a moves them with a radial closure movement.

The pipe is thus secured in a totally watertight manner and is resistant to tensile stresses. This embodiment makes utilization of an additional gasket around the pipe unnecessary, although it is possible to place such a gasket in one of the grooves 24 of pipe 23 inserted in the cylindrical 17 or frusto-conical 18 openings of the piece 2.

In addition to these advantages, this device has the special feature that upon unscrewing of the body 1 the pipe 23 is withdrawn from the body 2, due to the axial recession of the body 1 and, therefore, of the lugs 9, thus facilitating the operation of disassembling said pipe 23.

It is also important to stress that the connection device can be applied to pipes of different diameters, within certain limits, thanks to the flexibility of the lugs 9 and the frusto-conical opening 18, which compensate for small diameter differences of the pipes. Moreover, the absence in the interior of the bodies 1 or 2 of coaxial tubular extensions intended to be inserted inside the pipe to be connected avoids a reduction in the capacity of the latter.

Independent of the object of the invention shall be the materials used for the manufacturing of the components of the connection device, their shapes and dimensions and any other accessory detail, as long as they do not affect its essential nature.

Claims

1. Connection device for corrugated pipes, comprising at least two sleeve-like bodies (1, 2), each moulded in a single piece and having a certain amount of flexibility, which are complementary and can be coupled to each other by threaded engagement or another similar system, one of said bodies (1) having a plurality of flexible lugs (9) with teeth-like projections (10) at their ends, intended to remain secured in one of the ring-shaped grooves (24) of a corrugated pipe (23) due to the gripping action that the other body (2) exerts against the lugs upon coupling with the first body (1), characterized in that said lugs (9) extend inwards from a mouth (6) of the body (1), and are arranged forming a circular crown (7) spaced apart a certain distance from the inner side of the body (1), thus defining a ring-shaped gap (7a), while the other body (2) has a frustoconical opening (18) and a cylindrical extension (19) with a bevelled edge (16) to assist its insertion under pressure into said gap (7a), the inner diameter of said projection (19) being smaller than the outer diameter of the crown (7) formed by the lugs (9) and its thickness being greater than the width of said ring-shaped gap (7a), so that the cylindrical extension (19) compresses the lugs (9) against the outer surface of the corrugated pipe (23), thus keeping the tooth-shaped projections (10) secured into one of the grooves (24) thereof, in order to move the end of the pipe towards the frusto-conical opening (18), against which it fits forming a watertight seal.
2. Connection device as claimed in claim 1, characterized in that said body (1) provided with the crown (7) of lugs (9) has an inwardly bevelled edge (6) to guide the introduction of the pipe (23) inside the body, and is provided on its outer surface with projections and recesses to assist its handling in rotation.
3. Connection device for corrugated pipes, as claimed in Claim 1, characterized in that the body (2) com-

pressing the lugs (9) around the pipe (23) is provided with a polygonal nut-like outer surface (14).

4. Connection device for corrugated pipes, as claimed in Claim 1, characterized in that said two bodies (1,2) are provided with a mutually retaining device (20, 22) which engages them loosely in an optimum operating position, and in that they are supplied for use in this engaged condition.
5. Connection device for corrugated pipes, as claimed in Claims 1 and 4, characterized in that the body (1) provided with the crown (7) of lugs (9) on one end is provided with a slot (20) on the other end, while the other body (2) is provided with a projecting flexible tongue (22) for engagement into said slot (20).
